

Overview:

This data set consists of diagnostic criteria from 768 patients with similar characteristics (females 21 years or older and of Pima Indian heritage) and whether they have diabetes. It has the following features:

Outcome: This feature is 1 if the patient has diabetes and 0 if they do not.

Age: The patient's age in years.

DiabetesPedigreeFunction (DPF): A score which predicts the likelihood of diabetes based on family history.

BMI: Body mass index in kg/m^2

Insulin: 2-hour serum insulin in muU/ml.

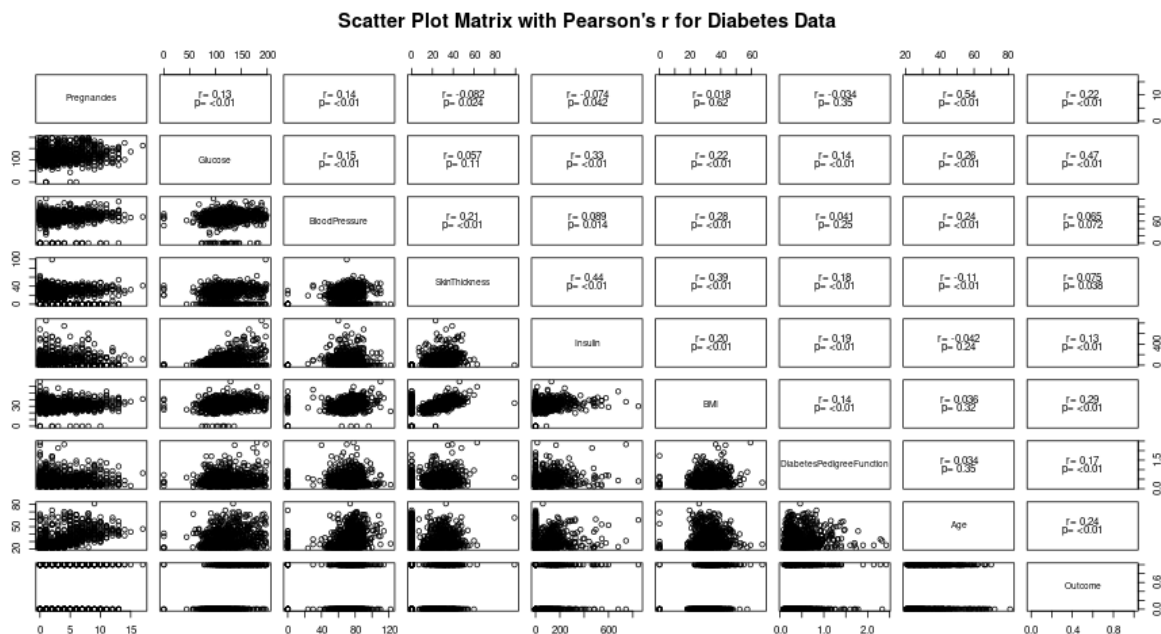

SkinThickness: Tricep skin fold thickness in mm.

BloodPressure: Diastolic blood pressure in mm Hg

Glucose: Plasma glucose concentration as determined by an oral glucose tolerance test.

Pregnancies: The number of times the patient has been pregnant.

Summary:

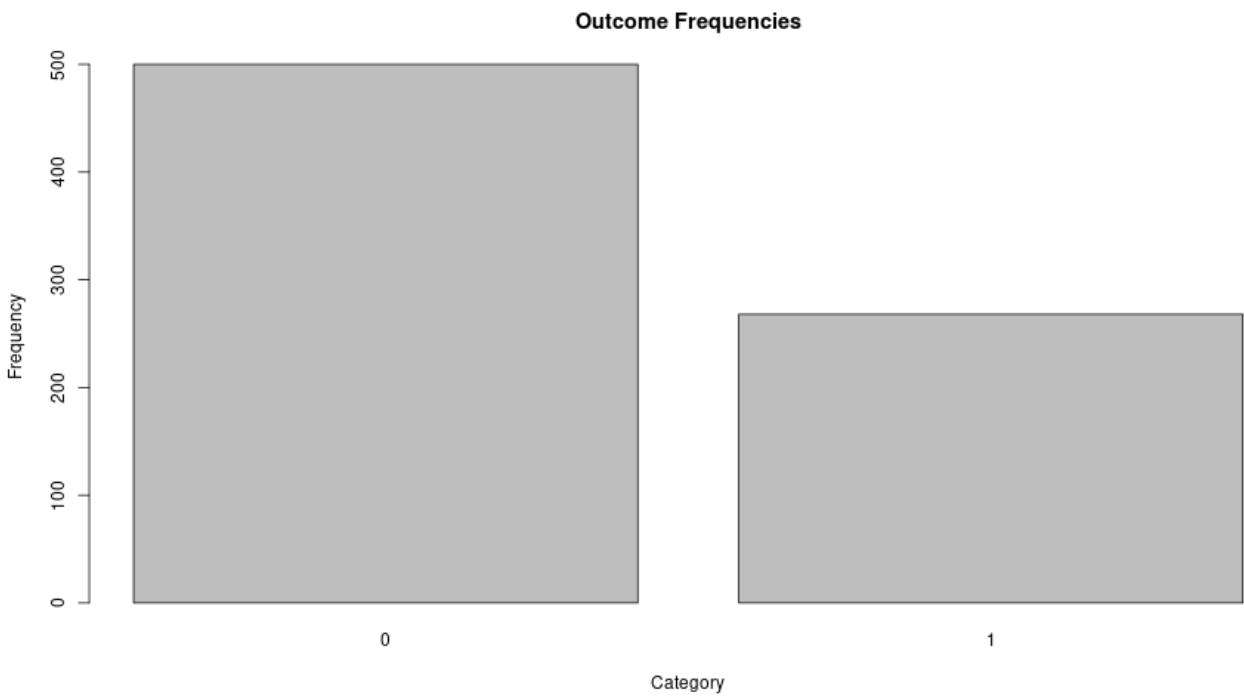

For the most part, the quality of this data seems to be good. The one exception is that certain tuples have measurements which don't make sense, such as those with a skin thickness or BMI of 0 mm. It is possible that some of these were rounded down, given that the skin thickness measurements are integers, but others might be substitutes for missing data.

Although this data set contains medical data, it lacks identifying information and most likely does not pose any privacy concerns.

The features which describe diagnostic criteria all seem to be useful without any cleanup or alteration. Since outcome describes a characteristic that patients either have or do not have, it may need to be replaced with a nominal feature that contains the same information.
